One of the worst things about cancer – and there are many contenders for that distinction – is that the disease can be quite stealthy. Too often, tumours develop undetected. If cancer goes undiscovered long enough for it to take root in an organ or spread through the body, it becomes a formidable foe for even the most sophisticated therapies. The best that people in this situation can hope for is to survive for a few more years.

The inadequacy of diagnostics helps to explain why, despite huge leaps forward in treatment, cancer is still responsible for roughly one in six deaths. Fortunately, cancer diagnosis is in the midst of rapid and transformative change. Studies of the intricacies of cancer genetics are providing scientists with the more nuanced understanding that, in effect, every cancer is a rare cancer (see page S10). And techniques for detecting tumours early are developing apace, as is other diagnostics research (S20).

Liquid biopsies, for example, are revolutionizing the early detection of cancer by allowing physicians to monitor the blood, instead of taking a tissue sample (S6); the task now is to put in place trials that will allow this technology to be used routinely in the clinic (S9). Machine-learning algorithms are also starting to become indispensable aids in diagnosis – artificial intelligence can recognize patterns that are too subtle for the human eye to detect (S14). Such technologies face their toughest test in pancreatic cancer, which is almost always caught too late to treat (S12).

The ability to detect cancer early, when it can be hard to tell how great a threat it will go on to pose, does, however, present a challenge to those designing screening programmes. Researchers are testing approaches to cut down on overdiagnosis and treatment of low-risk cancers while maintaining the health benefits of check-ups for, in particular, cancers of the breast and prostate (S2). Debates about screening protocols have led to widespread confusion about when and if testing should take place (S5). Screening is especially problematic in low- and middle-income countries, where medical infrastructure is lacking (S17).

Contents

S2 SCREENING
An uncertain diagnosis

S5 PERSPECTIVE
We need to know better to do better

S6 LIQUID BIOPSY
Taking cancer out of circulation

S9 PERSPECTIVE
The future of liquid biopsy

S10 GENETIC SEQUENCING
How cancer genomics is transforming diagnosis and treatment

S12 HARD-TO-TREAT CANCER
The pancreas problem

S14 ARTIFICIAL INTELLIGENCE
Another set of eyes for cancer diagnostics

S17 HEALTH CARE
Detecting cancer using limited resources

S20 CLINICAL TRIALS
Research round-up

About Nature Outlooks

Nature Outlooks are supplements to *Nature* supported by external funding. They aim to stimulate interest and debate around a subject of particularly strong current interest to the scientific community, in a form that is also accessible to policymakers and the broader public. *Nature* has sole responsibility for all editorial content – sponsoring organizations are consulted on the topic of the supplement, but have no influence on reporting thereafter (see go.nature.com/2NqAZ1d). All *Nature Outlook* supplements are

available free online at go.nature.com/outlook

How to cite our supplements

Articles should be cited as part of a supplement to *Nature*. For example: *Nature* Vol. XXX, No. XXXX Suppl., Sxx–Sxx (2020).
