Materials and Methods

All silylation reactions were assembled in an N₂-filled glovebox using oven-dried glassware and were stirred with Teflon-coated magnetic stirring bars. [Ir(cod)OME]₂ was obtained as a gift from Johnson Matthey and was used as received. Ru(PPh₃)₃Cl₂ was purchased from Strem and was used as received. 3,4,7,8-Tetramethyl-1,10-phenanthroline (Me₄phen) was purchased from Aldrich and was used as received. Diethylsilane (Et₂SiH₂) was purchased from Alfa Aesar and was used as received. Norbornene (nbe) was purchased from Aldrich and was used as received. Tetrahydrofuran (THF) was degassed by purging with nitrogen and then dried with a solvent purification system containing activated alumina. All other solvents and reagents were used as received, with the exception of dihydrolinalool, which was purified by bulb-to-bulb distillation. Half-saturated aq. solutions refer to a freshly prepared 1:1 v/v mixture of the corresponding saturated aq. solution and deionized water. Reaction temperatures above 23 °C refer to temperatures of an aluminum heating block, which were either controlled by an electronic temperature modulator, or controlled manually and monitored using a standard alcohol thermometer. Silica gel chromatography was performed using a Teledyne Isco CombiFlash® Rf system with RediSep Rf Gold™ columns. Kugelrohr distillation was performed using a Büchi Glass Oven B-580. ¹H NMR spectra were recorded on Varian UI-500NB, U-500 and VXR-500 spectrometers. ¹³C NMR spectra were recorded on Varian U-500 and VXR-500 spectrometers with ¹³C operating frequencies of 125 MHz. Chemical shifts (δ) are reported in ppm relative to the residual solvent signal (δ = 7.26 for ¹H NMR and δ = 77.16 for ¹³C NMR). ¹⁹F NMR spectra were recorded on a Varian U-500 spectrometer with a ¹⁹F operating frequency of 470 MHz. Data for ¹H NMR spectra are reported as follows: chemical shift (multiplicity, coupling constants, number of hydrogens). Abbreviations are as follows: s (singlet), d (doublet), t (triplet), q (quartet), m (multiplet), br (broad). GC-MS data were obtained on an Agilent 6890-N GC system containing an Alltech EC-1 capillary column and an Agilent 5973 mass selective detector. High-resolution mass spectral data were obtained from the University of Illinois SCS Mass Spectrometry Laboratory.
Experimental Procedures

Synthesis of Substrates: Substrates Prepared by Heck Coupling

General procedure for Heck coupling of aryl iodides: The general conditions described by Jeffrey\textsuperscript{1} were employed with slight modification. In an N\textsubscript{2}-filled glovebox, a 20 mL screw-capped vial was charged with Pd(OAc)\textsubscript{2} (30 \( \mu \)mol, 1 mol %), KHCO\textsubscript{3} (7.5 mmol, 2.5 equiv), tetrabutylammonium chloride (3.0 mmol, 1.0 equiv), aryl iodide (3.0 mmol, 1.0 equiv), 1-penten-3-ol (6.0 mmol, 2.0 equiv) and MeCN (6.0 mL). A stir bar was added, and the vial was capped with a Teflon-lined screw cap and placed in a pre-heated aluminum block at 50 °C (CAUTION: CO\textsubscript{2} evolution!). Upon complete consumption of the aryl iodide (as determined by GC-MS analysis, generally 12-24 h), the stir bar was removed, and the reaction mixture was directly concentrated by rotary evaporation. The resulting residue was dissolved in a mixture of hexanes and EtOAc,\textsuperscript{2} filtered through a short plug of SiO\textsubscript{2}, and concentrated. The residue was adsorbed onto SiO\textsubscript{2} and purified by silica gel chromatography to provide the ketone product.

General procedure for Heck coupling of aryl bromides: In an N\textsubscript{2}-filled glovebox, a 20 mL screw-capped vial was charged with Pd(OAc)\textsubscript{2} (30 \( \mu \)mol, 1 mol %), KHCO\textsubscript{3} (7.5 mmol, 2.5 equiv), tetrabutylammonium chloride (3.0 mmol, 1.0 equiv), aryl bromide (3.0 mmol, 1.0 equiv), 1-penten-3-ol (6.0 mmol, 2.0 equiv) and DMF (6.0 mL). A stir bar was added, and the vial was capped with a Teflon-lined screw cap and placed in a pre-heated aluminum block at 120 °C (CAUTION: CO\textsubscript{2} evolution!). Upon complete consumption of the aryl bromide (as determined by GC-MS analysis, generally 12-24 h), the reaction mixture was directly loaded onto a short plug of SiO\textsubscript{2}. The product was eluted with 80:20 hexanes/EtOAc and concentrated. The residue was dissolved in Et\textsubscript{2}O (75 mL). The resulting solution was washed (3 x 30 mL water, then 30 mL brine), dried (MgSO\textsubscript{4}) and
concentrated. The crude product was then adsorbed onto SiO$_2$ and purified by silica gel chromatography.

**General Procedures**

**General procedure for Ir-catalyzed silylation of alcohols or ketones:** In an N₂-filled glovebox, ca. 1.0 mmol of the alcohol or ketone substrate was weighed into a one-dram screw-capped vial. A stir bar was added, and the substrate was dissolved in THF (0.50
mL). The resulting solution was treated first with a freshly prepared stock solution of
[Ir(cod)OMe]_2 (0.5 µmol, 0.05 mol %, unless otherwise specified) in THF (0.50 mL) and
then neat Et₂SiH₂ (1.20 mmol). The vial was capped with a Teflon-lined screw cap, and
the resulting solution was stirred in the glovebox at room temperature (unless otherwise
specified) until complete conversion to the corresponding diethyl(hydrido)silyl ether was
observed, as determined by GC, GC-MS or ¹H NMR analysis (generally 5-12 h)
(CAUTION: H₂ evolution in the case of alcohol substrates!).

**General procedure for Ru-catalyzed silylation of alcohols:** In an N₂-filled glovebox,
ca. 1.0 mmol of the alcohol substrate was weighed into a one-dram screw-capped vial. A
stir bar was added, and the substrate was dissolved in a freshly prepared stock solution of
Ru(PPh₃)₃Cl₂ (2.0 µmol, 0.2 mol %) in PhH or PhMe (1.0 mL). The resulting solution
was treated with neat Et₂SiH₂ (1.20 mmol), and the vial was capped with a Teflon-lined
screw cap. The vial was then removed from the glovebox, placed in a pre-heated
aluminum heating block at 50 °C and stirred until complete conversion to the
corresponding diethyl(hydrido)silyl ether was observed, as determined by GC or GC-MS
analysis (generally overnight) (CAUTION: H₂ evolution!).

**General procedure for Ir-catalyzed intramolecular aliphatic silylation:** In an N₂-
filled glovebox, the crude reaction mixture containing the diethyl(hydrido)silyl ether (ca.
1.0 mmol) and solvent was placed under high-vacuum for 1 h (the stir bar was
temporarily removed during this operation to prevent bumping). The stir bar was
replaced, and the concentrated diethyl(hydrido)silyl ether was then sequentially treated
with freshly prepared stock solutions of norbornene (1.20 mmol) in THF (1.0 mL) and
[Ir(cod)OMe]₂ (5.0 µmol, 0.5 mol %) in THF (0.50 mL), and then with a slurry of
Me₄phen (12.5 µmol, 1.25 mol %) in THF (0.50 mL). The Teflon-lined screw cap was
replaced, and the resulting solution was stirred in the glovebox for 1 h (to ensure
complete formation of the active Ir species). The vial was then removed from the
glovebox, placed in a pre-heated aluminum block at the specified temperature and stirred
for the indicated period of time.
**General procedure for Tamao-Fleming oxidation of oxasilolanes**: On the bench top, the crude reaction mixture containing the oxasilolane (ca. 1.0 mmol) in THF (2.0 mL) was transferred to a 20 mL screw-capped vial via pipette and sequentially treated with MeOH (2.0 mL), KHCO₃ (2.5 mmol) and H₂O₂ (30% solution in H₂O, 10 mmol). The vial was sealed with a Teflon-lined screw cap, and the resulting mixture was stirred overnight at 50 °C (unless otherwise specified) (CAUTION: CO₂ evolution!). The reaction was carefully quenched with aq. NaHSO₃ (30 mL) (CAUTION: further CO₂ evolution!), and the resulting mixture was extracted with EtOAc (30 mL, then 2 x 15 mL). The combined organic layers were washed (30 mL 1 N HCl, then 30 mL sat. NaHCO₃), dried (MgSO₄), filtered through Celite, and concentrated to provide the crude diol.

**General procedure for Tamao-Fleming oxidation of oxasilolanes with added KF**: On the bench top, the crude reaction mixture containing the oxasilolane (ca. 1.0 mmol) in THF (2.0 mL) was transferred to a 20 mL screw-capped vial via pipette and sequentially treated with KHCO₃ (2.5 mmol), a solution of KF (2.5 mmol) in MeOH (2.0 mL) and H₂O₂ (30% solution in H₂O, 10 mmol). The vial was sealed with a Teflon-lined screw cap, and the resulting mixture was stirred overnight at 50 °C (CAUTION: CO₂ evolution!). The reaction was carefully quenched with aq. Na₂SO₃ (20 mL), and the resulting mixture was extracted with EtOAc (3 x 30 mL, then 2 x 15 mL). The combined organic layers were dried (MgSO₄), filtered through Celite, and concentrated to provide the crude diol.

**General procedure for diacylation of diol intermediates**: The crude diol was dissolved in 4:1 CH₂Cl₂/Et₃N (ca. 0.3 M), and the resulting solution was treated with DMAP (0.05 equiv) and Ac₂O (3.0 equiv). After being stirred at room temperature overnight, the reaction mixture was filtered through SiO₂ (rinsing with EtOAc) and concentrated. The resulting residue was adsorbed onto SiO₂ and purified by silica gel chromatography to provide the diacetate product.
General procedure for monoacylation of diol intermediates:
The crude diol was dissolved in 5:1 CHCl₃/Et₃N (ca. 0.3 M), and the resulting solution was treated with Ac₂O (1.5 equiv). After being stirred at room temperature overnight, the reaction mixture was filtered through SiO₂ (rinsing with EtOAc) and concentrated. The resulting residue was adsorbed onto SiO₂ and purified by silica gel chromatography to provide the monoacetate product.

Oxasilolane 6: In an N₂-filled glovebox, tetrahydrolinalool (792 mg, 5.00 mmol) was weighed into a 20 mL screw-capped vial. A stir bar was added, followed by THF (3.0 mL). The resulting solution was treated first with a freshly prepared solution of [Ir(cod)OMe]₂ (1.3 mg, 2.0 µmol, 0.04 mol %) in THF (2.0 mL) and then neat Et₂SiH₂ (496 mg, 5.62 mmol). The vial was capped with a Teflon-lined screw cap, and the resulting solution was stirred in the glovebox at room temperature for 15 h, at which point GC-MS analysis indicated full conversion to diethyl(hydrido)silyl ether 5. GC/MS: m/z 243.1 (0.1%, [M-H]+), 229.2 (6.4%, [M-Me]+), 215.2 (59.4%, [M-Et]+), 159.1 (100.0%, [M-C₆H₁₃]+). The volatile materials were removed by placing the reaction mixture directly under high vacuum for 4 h (the stir bar was temporarily removed during this operation to prevent bumping). The stir bar was replaced, and the concentrated diethyl(hydrido)silyl ether was then sequentially treated with freshly prepared solutions of norbornene (565 mg, 6.00 mmol) in THF (6.0 mL) and [Ir(cod)OMe]₂ (7.3 mg, 11 µmol, 0.22 mol %) in THF (2.0 mL), and then with a slurry of Me₄phen (8.3 mg, 35 µmol, 0.70 mol %) in THF (2.0 mL). The Teflon-lined screw cap was replaced, and the resulting solution was stirred in the glovebox for 3 h (to ensure complete formation of the active Ir species). The vial was then removed from the glovebox, placed in a pre-heated aluminum block at 80 °C, and the reaction was stirred for 43 h. The reaction mixture was then allowed to cool to room temperature, and the solvent was removed by rotary evaporation. The resulting residue was purified by Kugelrohr distillation (55 mTorr, 70 °C) to give 1.10 g (91%) of oxasilolane 6 as a colorless oil.

(2) A significant amount of the residue remaining after removal of the solvent is insoluble in hexanes/EtOAc. Thus, after addition of hexanes/EtOAc, the remaining solid was broken up with the aid of a spatula and subsequently loaded onto the SiO$_2$ plug as a suspension.
