<sup>1</sup> day of year with first spring frost in the North region

<sup>2</sup> day of year with first spring frost in the Central region

<sup>3</sup> day of year with first spring frost in the South region

<sup>4</sup> day of year with first spring frost in the West region

<sup>5</sup> day of year with last fall frost in the North region

<sup>6</sup> day of year with last fall frost in the Central region

<sup>7</sup> day of year with last fall frost in the South region

<sup>8</sup> day of year with last fall frost in the West region

<sup>9</sup> Northern Hemisphere annual mean temperature

<sup>10</sup> regional mean temperature for spring or fall according to column heading

<sup>11</sup> circulation index corresponding to frost timing index in the column heading, meaning  $C_{SN}$  for  $S_N$ ,  $C_{SC}$  for  $S_C$ , etc.

<sup>12</sup> Northern Hemisphere mean temperature for March-May ( $T_{MAM}$ ) or September-November ( $T_{SON}$ ) according to column heading

<sup>13</sup> global annual mean temperature

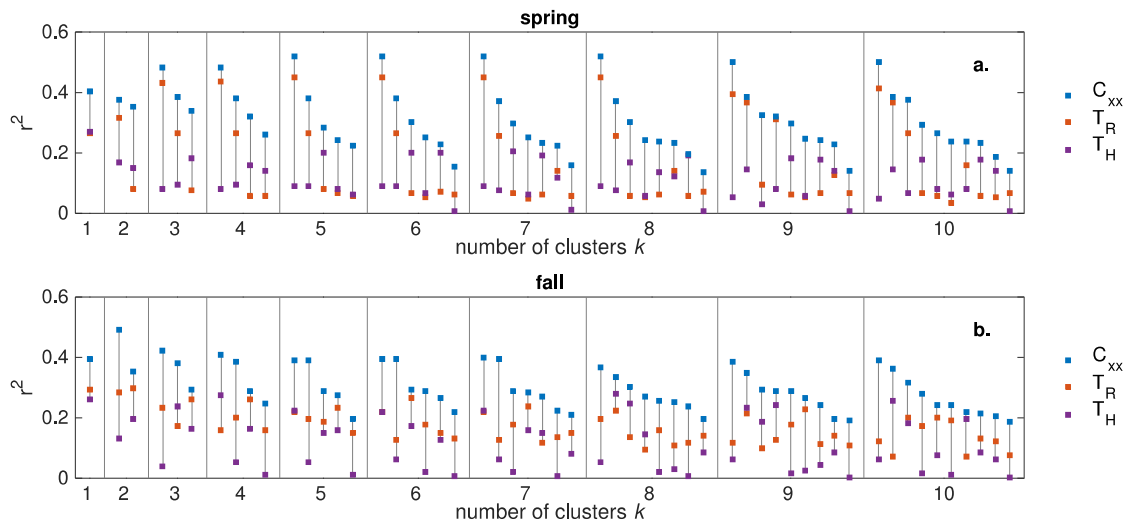

<sup>14</sup> Pacific North American Pattern Index for March-May or September-November according to column heading

<sup>15</sup> North Atlantic Oscillation Index for March-May or September-November according to column heading

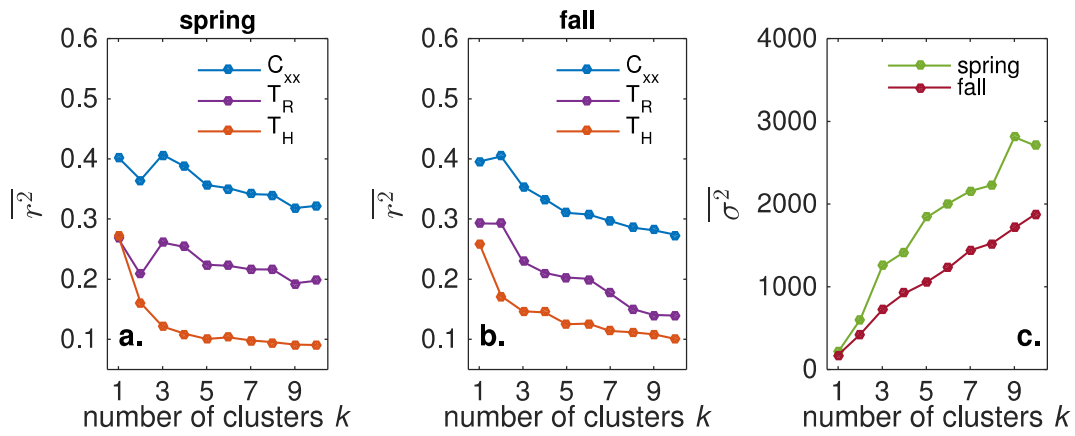

<sup>16</sup> Atlantic Multidecadal Oscillation Index for March-May or September-November according to column heading

<sup>17</sup> Southern Oscillation Index for March-May or September-November according to column heading

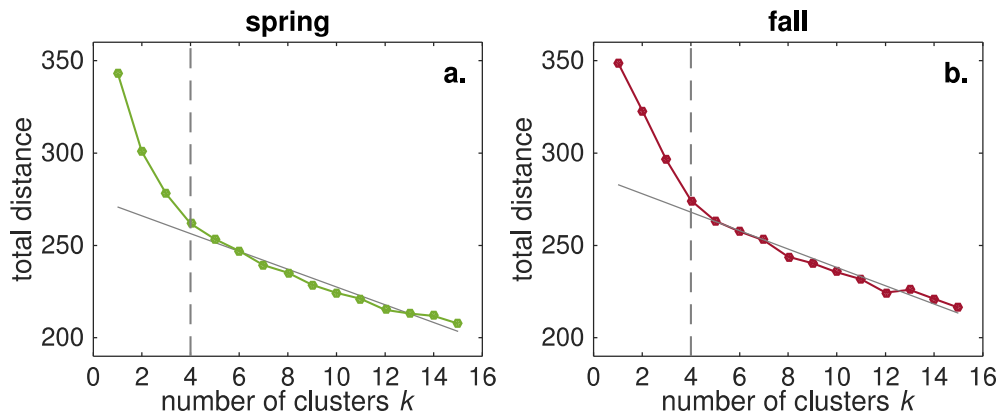

**Supplementary Table 1.** Squared correlation between indices of frost timing, temperature, and circulation, with bold indicating statistical significance and asterisk indicating negative correlation.

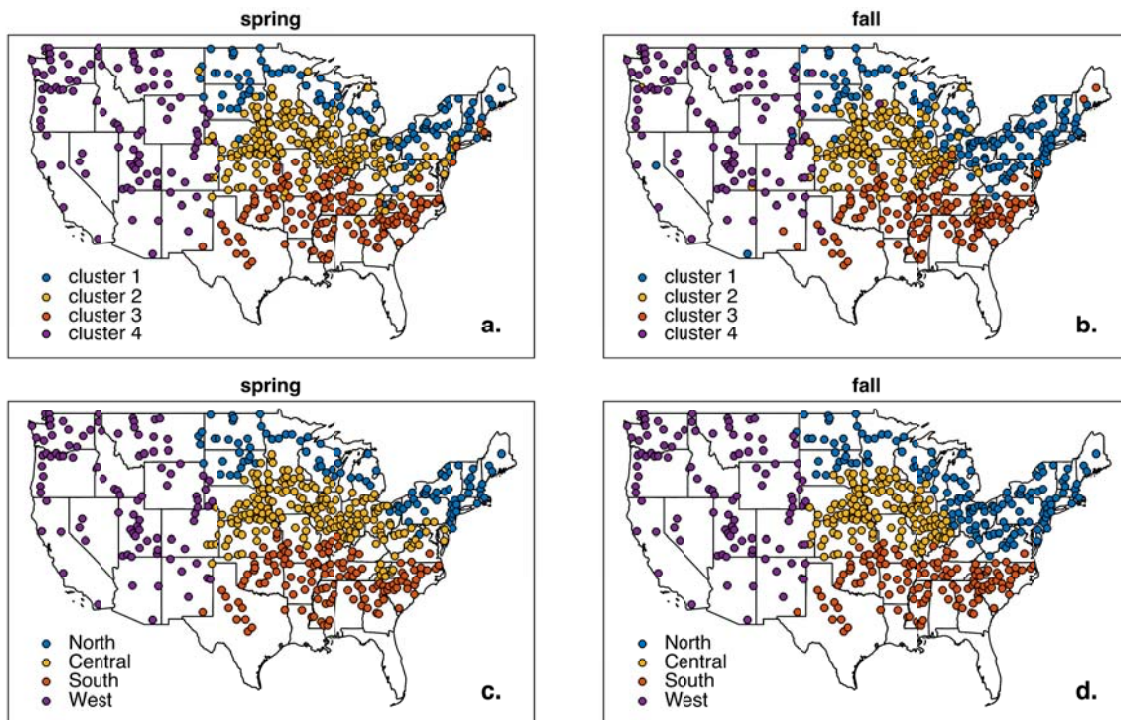

**Supplementary Figure 1 | Robustness to number of clusters.** (a) For values , the squared correlation between the day of year with last spring frost in each of the  $k$  regions and the following three time series: the circulation index for the region ( $C_{xx}$ ), mean temperature in the region during spring ( $T_R$ ), and hemispheric annual mean temperature ( $T_H$ ). (b) Same as (a), but for the day of year with first fall frost.

**Supplementary Figure 2 | Variability versus number of clusters.** (a) For number of clusters  $k$  in the range , the area-weighted mean squared correlation ( $\overline{r^2}$ ) between the day of year with last spring frost in each of the  $k$  regions and the following three time series: the circulation index specific to the region ( $C_{xx}$ ), seasonal mean temperature in the region ( $T_R$ ), and hemispheric annual mean temperature ( $T_H$ ). (b) Same as (a), but for the day of year with first fall frost. (c) The area-weighted mean variance of the day of year with last spring frost and first fall frost.

**Supplementary Figure 3 | Distance versus number of clusters.** (a) For clustering of the time series indicating day of year with last spring frost over the conterminous U.S., the curve indicates the total distance versus number of clusters  $k$ . Distance was defined as  $(1 - R)$ , where  $R$  is the correlation distance (Methods section). A least-squares fit to the values over is shown by the gray line, and the vertical line at 4 indicates the value of  $k$  used for the main results. (b) Same as (a), but for clustering of the first day of year with fall frost.

**Supplementary Figure 4 | Objective clustering of stations. (a)** Objective  $k$ -means clustering of the day of year with last spring frost ( $k=4$ ; years 1920-2012). **(b)** Objective  $k$ -means clustering of the day of year with first fall frost ( $k=4$ ; years 1920-2012). **(c)** As in (a), but outliers were eliminated by assigning each station the mode of the cluster assignments of its seven nearest neighbors. **(d)** As in (b), but outliers were eliminated by assigning each station the mode of the cluster assignments of its seven nearest neighbors.
